

ISAAK

Classifying vessel shapes

using automated shape extraction and unsupervised classification

motivation

previous approaches

Shape Extraction

Shape Analysis 1: PCA & hclust

Shape Analysis 2: t-sne & hdbscan

Case study 1: Bell Beakers of the Iberian Peninsula

Case study 2: Neolithic Swiss Ceramic

motivation

shape vs. decoration for typology

levels of pottery design

Tendencies:

criteria	shape	decoration
functional dependency	strong	weak
dependency on local ressources	stronger	weak
moment of determination	from the beginning	finished product
ad hoc changes	difficult	easy
more reflecting	practised reality	imagined reality
design decision	more collective	more individual
homogeneity	more convergent	more divergent
degrees of freedom	smaller	higher
category of style	more isochrestic	more emblemic
unit of analysis	ideal type	singularity

Phases of ceramic production

Design

- imagined and intended
- concept of a shape (incl. attached parts, eg. handles)
- ideal type
- **social bounded options for creativity**

'style of action'

- learned, habitual movements, manipulations, routines
- at all stages of the *chaîne opératoire*
- instantiation reflecting the characteristics of the material
- **limited or prescribed options for creativity**

'material style'

- physical traces and effects in the material
- Characteristics of the vessel
- finished object
- **material induced alterations of the original design possible**

using vessel shapes to identify underlying large scaled ‘communities of practice’ in production and consumption

- more related to covert communication structures, habitus and similar (economic) practises
- ‘better measurable’ from a practical quantitative perspective

previous approaches

using specific locations

- Koch 1998

'Holistic' approaches

- Mom 2005
- Chapman et al., 2006
- Keogh et al., 2009

Shape Extraction

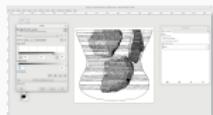

'by hand': workflow

load

clean

enhance contrast

close gaps

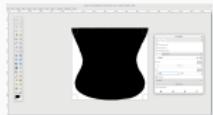

fill inside black

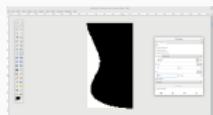

turn bw (bitmap)

rotate

crop

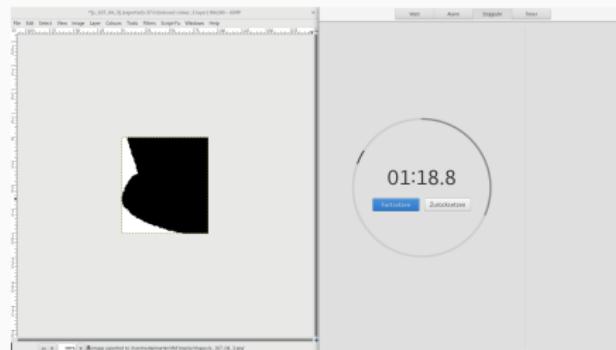

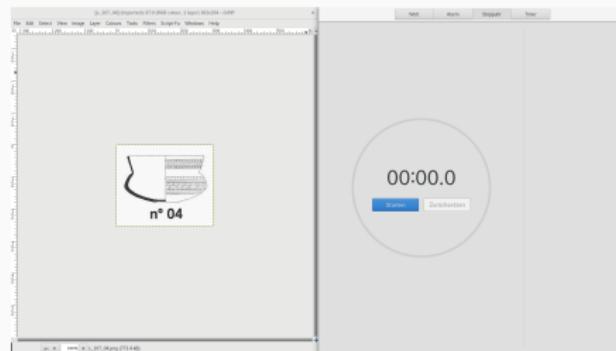

split in half

scale to resolution (100px)

'by hand': speed

Adaptive Contour Motivation

- 1:30 min for 800 images -> 20 hours
 - automation makes sense!
- scanned vessel drawings not trivial
 - might have holes (dashed lines)
 - might have additional image components beside the vessels
- no simple image segmentation with background color and floodfill possible

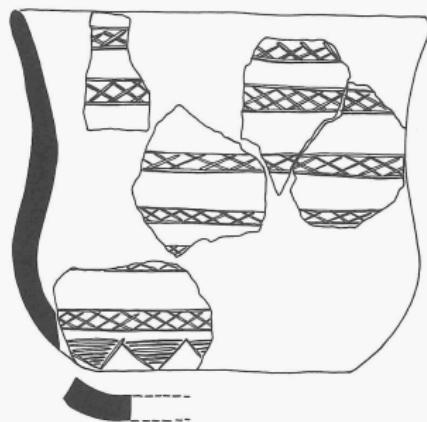

Figure 1: Bell Beaker (Harrison 1977)

Adaptive Contour: what is it

Active contour model, also called ***snakes***, is a framework in computer vision for delineating an object outline from a possibly noisy 2D image. The snakes model is popular in computer vision, and snakes are greatly used in applications like object tracking, ***shape recognition***, segmentation, edge detection and stereo matching. Wikipedia

Active contour with Bell Beakers

See shapAAR vignette

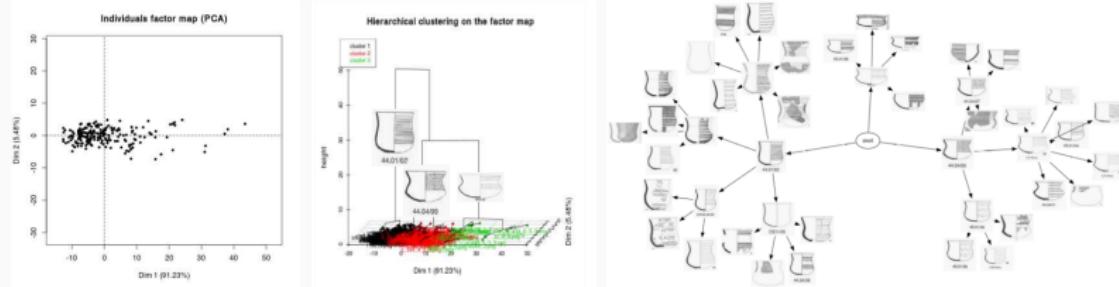

<https://github.com/ISAAKiel/shapAAR/blob/master/vignettes/object-extraction.md>

	Image preparation	bw, blur
	Image segmentation	active_contour
	Selecting the biggest object	EBImage
	Rectify and crop	get Bounding box, rotate upright, crop
	half and side mean	split in middle, mean left-right

Shape Analysis 1: PCA & hclust

approach/workflow

- using profile distances + additional nominal variables as input
- conduct PCA
- using hclust (euclidean/Ward) to cluster
- package FactoMinR: HCPC with automatical cut (number of clusters according to higher relative loss of inertia)
- for individual clusters, repeat with cluster members as new dataset (usually 3 levels)

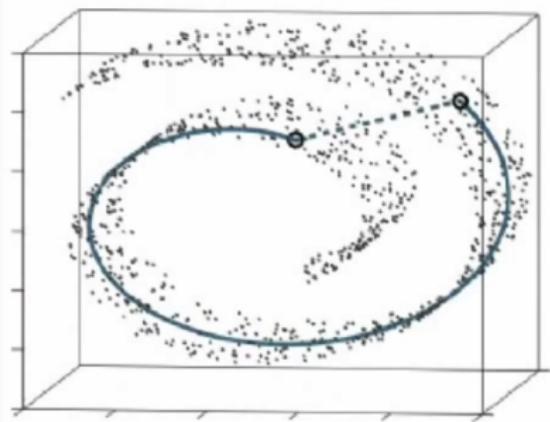

problems

- non-metric (non-euclidean) variables not considered correctly
- all vessels had to belong to one cluster (hand made ceramics)
- global dissimilarity resulted in suboptimal separation

Shape Analysis 2: t-sne & hdbSCAN

t-Distributed Stochastic Neighbor Embedding

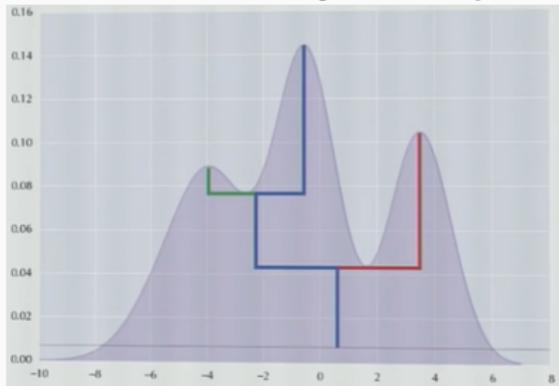

Challenge

- high dimensional non-linear data distribution
- consider not the global, but the local neighbourhood (contrasting PCA)

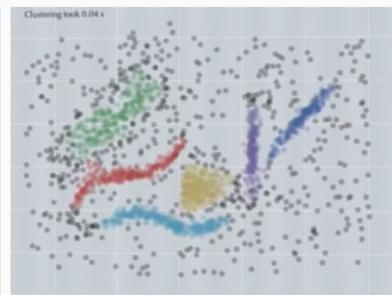

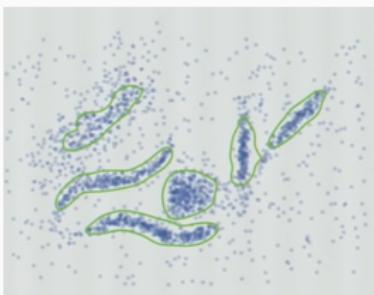

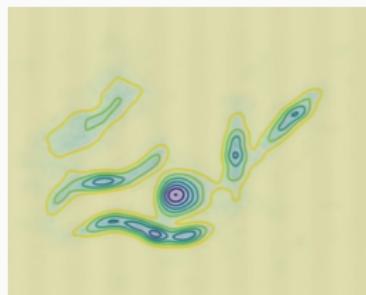

Figure 2: van der Maaten 2008; 2009; 2012; 2014;
<https://lvdmaaten.github.io/tsne/>
<https://www.youtube.com/watch?v=RJVL80Gg3IA>

Hierarchical Density-Based Spatial Clustering of Applications with Noise

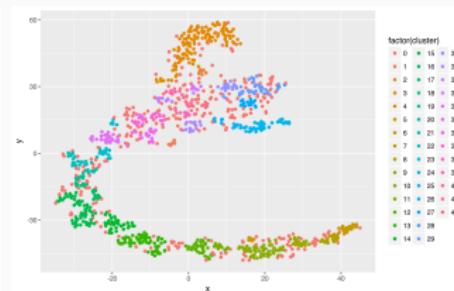

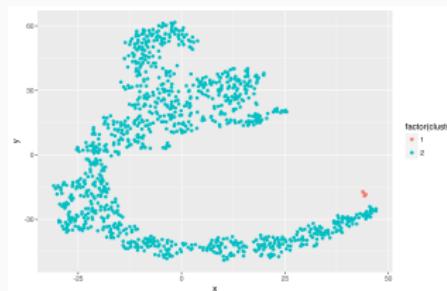

Benefits:

- separating non-circular clusters
- 'identification' and exclusion of noise (hand made ceramics!)

approach/workflow

- using profile distances + additional nominal variables as input
- conduct t-sne
- using hdbscan to cluster
- package Rtsne: conduct t-sne
 - `Rtsne(as.matrix(shapes), perplexity=30, dims=2, theta = 0)`
- package dbscan: conduct hdbscan on t-sne result
 - `hdbscan(this_res_sne, minPts = 5)`
- for individual clusters, repeat with cluster members as new dataset (usually only 2 levels)

stochastic nature of t-sne

Problem

- t-sne is a stochastic algorithm
 - results from two t-sne runs might differ
 - accordingly clustering might also differ

solution

- consensus clustering
 - repeat clustering for n times (101)
 - mark co-occurrence of objects in cluster
 - make final cluster solution on majority voting

Case study 1: Bell Beakers of the Iberian Peninsula

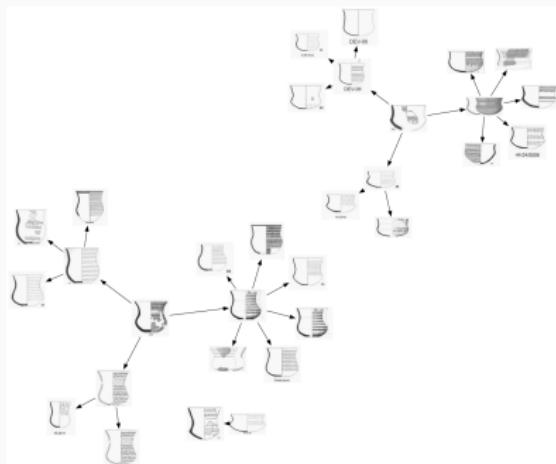

Dataset

- 213 specimens
- Collected from 5 publications
 - Leisner/Leisner 1956
 - Harrison 1977
 - García Rivero 2008
 - Rojo-Guerra et al. 2005
 - Prieto-martinez/Salanova 2011
- Only ceramics with full (preserved or reconstructed) profiles
- Only beakers and carinated bowls

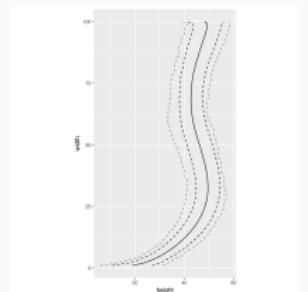

Results HCPC

- Separation Beakers/Carinated Bowls on first Level
- additionally small group with low belly break

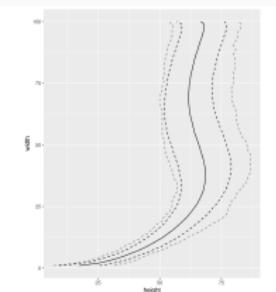

mean profile per cluster HCPC

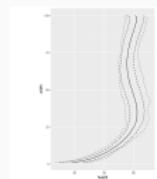

Cluster 1

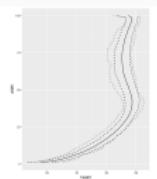

Cluster 2

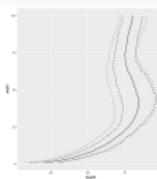

Cluster 2.1

Cluster 2.2

Cluster 2.3

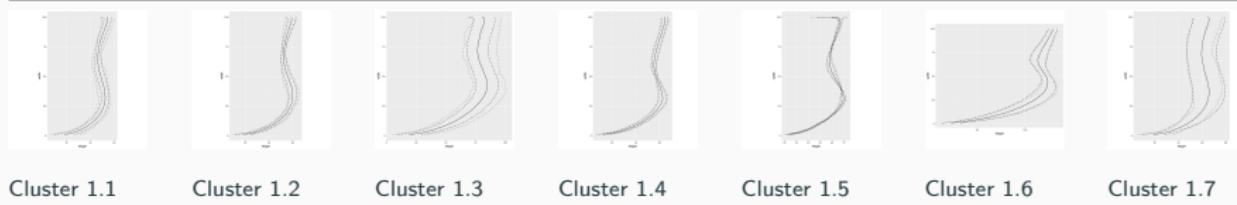

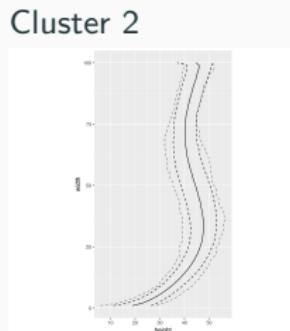

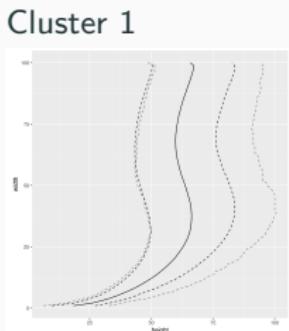

Results tsne_hdbscan

- Separation Slim Beakers/Stout Beakers + Carinated Bowls on first Level
- Separation Beakers/Bowls on second level

mean profile per cluster tsne_hdbscan

Resume Case Study 1

with t-sne and hdbscan

- finer separation of classes early
- profile curvature has more impact

but in general at this complexity level both approaches are feasible/comparable

Case study 2: Neolithic Swiss Ceramic
